

I am aiming for a grade of (D). This application, in the backend, has an API related to countries. When you start the app, you can add a country along with some specifications, including the zip code and continent. I have implemented CRUD operations for countries, as shown in Figure 1. After entering the desired country, click the (Add Country) button, and the object will be saved and displayed.

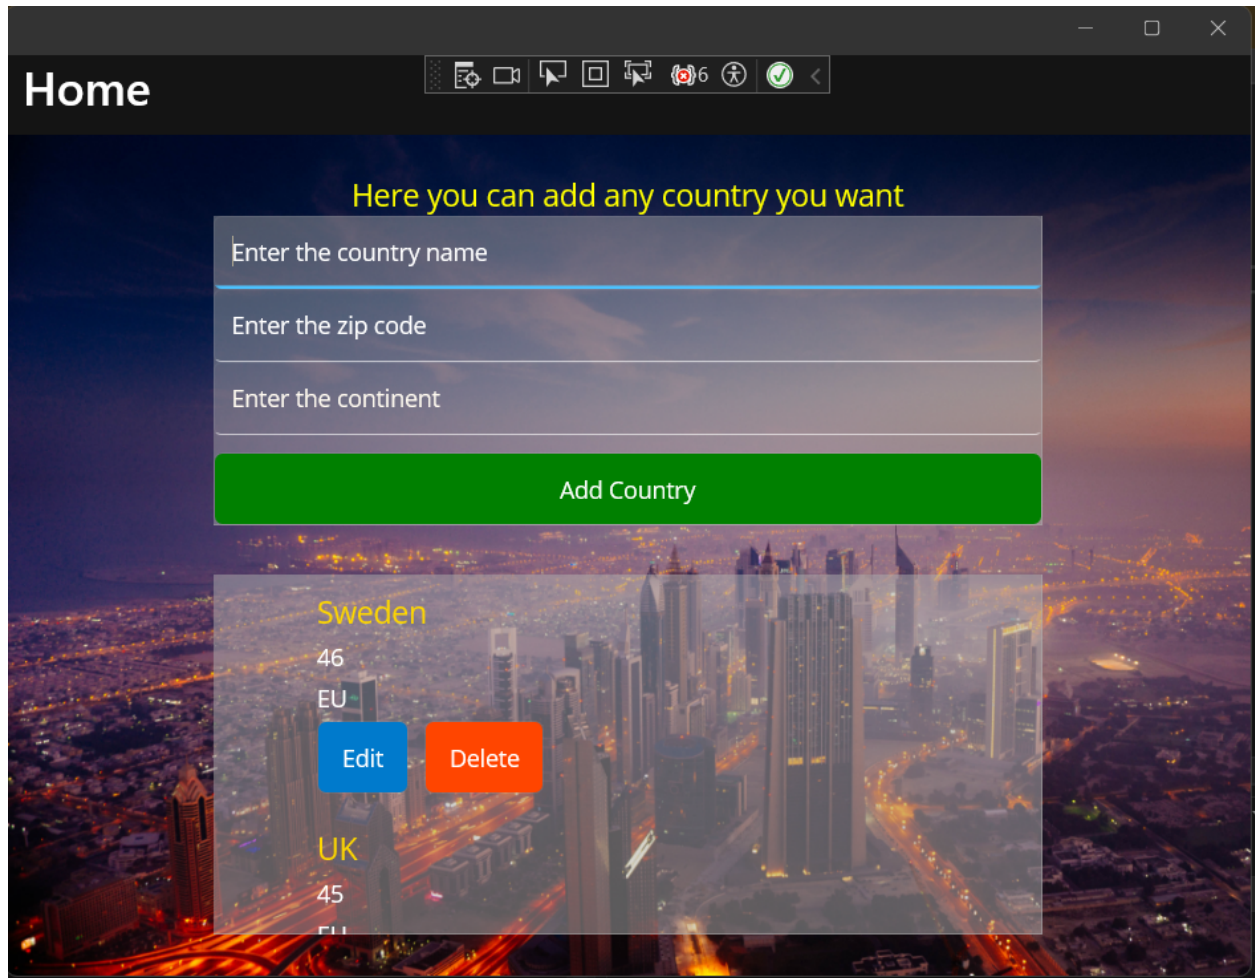

Figure 1

In Figure 2, when you click on the edit button, another page will open, allowing you to view the previous object. This makes it easier for the end user to edit the attributes with a clear understanding of how they are currently configured. Once you are done editing the object, click on save button and the edited object will be saved.

Figure 2

In this figure 3 you can easily delete any country you want and a message will be displayed in order to ensure if you want truly to delete the object.
